SATURATED STEAM, AND OTHER VAPORS.

A COMPARISON of the several tables of the properties of saturated steam, expressed in English units, reveals discrepancies of considerable magnitude; and investigation shows that, while all are in some manner founded on the experiments of Regnault, various methods of calculation have been used, and in some cases other experimental data have been employed. A review of the whole subject, in connection with the preparation of notes on thermodynamics for the use of the students of the Massachusetts Institute of Technology, made it seem important to calculate a set of tables, to accompany those notes, founded on the best and most recent data.

In presenting the tables for general use, it appears proper to state in full the data and the methods of calculation employed, so that each one may see the degree of accuracy and correctness of the tables, and the reliance to be placed on them.

Tables of the properties of other vapors have been added, which will be discussed hereafter.

Pressure of Saturated Steam.—As a conclusion from all the experiments on the tension of saturated steam, Regnault gives, in the *Mémoires de l'Institut de France, etc., Tome XXI.*, the following data:—

| TEMPERATURE | PRESSURE |
|-------------|-----------------|
| C. | MM. OF MERCURY. |
| —32 | 0.32 |
| —16 | 1.29 |
| 0 | 4.60 |
| 25 | 23.55 |
| 50 | 91.98 |
| 75 | 288.50 |
| 100 | 760.00 |
| 130 | 2030.0 |
| 160 | 4651.6 |
| 190 | 9426. |
| 220 | 17390. |

From these data he calculated, by the aid of seven-place logarithms, the following formulæ, which give the pressure in millimetres of mercury for any temperature in degrees Centigrade:—

A. For steam from -32° to 0° C.

$$p = a + ba^n.$$

$$a = -0.08038.$$

$$\log b = 9.6024724 - 10.$$

$$\log a = 0.033398.$$

$$n = 32^{\circ} - t.$$

B. For steam from 0° to 100° C.

$$\log p = a - ba^n + c\beta^n.$$

$$a = 4.7384380.$$

$$\log b = 0.6116485.$$

$$\log c = 8.1340339 - 10.$$

$$\log a = 9.9967449 - 10.$$

$$\log \beta = 0.006865036.$$

$$n = t.$$

C. For steam from 100° to 220° C.

$$\log p = a - ba^n + c\beta^n.$$

$$a = 5.4583895.$$

$$\log b = 0.4121470.$$

$$\log c = 7.7448901 - 10.$$

$$\log a = 9.997412127 - 10.$$

$$\log \beta = 0.007590697.$$

$$n = t - 100.$$

D. For steam from -20° to 220° C.

$$\log p = a - ba^n - c\beta^n.$$

$$a = 6.2640348.$$

$$\log b = 0.1397743.$$

$$\log c = 0.6924351.$$

$$\log a = 9.994049292 - 10.$$

$$\log \beta = 9.998343862 - 10.$$

$$n = t + 20.$$

By aid of the formulæ *A* and *B*, Regnault calculated and recorded tables of the pressures of saturated steam for temperatures from -32° to 100° C. The formula *D* was calculated from the data given above for the temperatures -20° , $+40^{\circ}$, 100° , 160° , and 220° C., and was intended to represent the whole range of experiments. By this formula, instead of formula *C*, he calculated the pressures set down in his tables for temperatures from 100° C. to 220° C.

that differ but little from those that will be given later. Some of the more recent tables in the French system were calculated by his equations.

Equations for the Pressure of Steam at Paris. — In view of the preceding statements, it appeared desirable to re-calculate the constants for Equations *B* and *C*, with a degree of accuracy that should exclude any doubt as to the reliability of the results. Accordingly, the logarithms required were taken from Vega's ten-place table, and then the remainder of the calculations were carried on with natural numbers, checking by independent methods, with the following results: —

B. For steam from 0° to 100° C.

$$\log p = a - ba^n + c\beta^n.$$

$$a = 4.7393622142.$$

$$\log b = 0.6117400190.$$

$$\log c = 8.1320378383 - 10.$$

$$\log \alpha = 9.996725532820 - 10.$$

$$\log \beta = 0.006864675924.$$

$$n = t.$$

C. For steam from 100° to 220° C.

$$\log p = a - ba^n + c\beta^n.$$

$$a = 5.4574301234.$$

$$\log b = 0.4119787931.$$

$$\log c = 7.7417476470 - 10.$$

$$\log \alpha = 9.99741106346 - 10.$$

$$\log \beta = 0.007642489113.$$

$$n = t - 100.$$

To show the degree of accuracy attained, the following tables are given: —

EQUATION *B*.

| <i>t</i> . | <i>p</i> . | LOG <i>p</i> FROM TABLE OF LOGARITHMS. | LOG <i>p</i> CALCULATED BY EQUATION. |
|------------|------------|---|---|
| 0 | 4.60 | 0.6627578317 | |
| 25 | 23.55 | 1.3719909115 | 1.37199097 |
| 50 | 91.98 | 1.9636934052 | 1.96369346 |
| 75 | 288.50 | 2.4601458175 | 2.46014587 |
| 100 | 760 | 2.8808135923 | 2.88081365 |

EQUATION *C*.

| <i>t</i> . | <i>p</i> . | LOG <i>p</i> FROM TABLE OF LOGARITHMS. | LOG <i>p</i> CALCULATED BY EQUATION. |

| 100 | 760.00 | 2.8808135923 | |

C and the numerical work was not carried to so large a number of decimal places. For the calculation of tables, the constants are carried to seven places of significant figures only; this gives six significant figures in the result, of which five are recorded in the table.

Pressure of Steam at Latitude 45° . — French System. — It is customary to reduce all measurements to the latitude of 45° , and to sea-level. The standard thermometer should then have its boiling and freezing points determined under, or reduced to such conditions. The value of g , the acceleration due to gravity, is, at Paris, latitude $48^\circ 50' 14''$ and 60 metres above sea-level, 9.809218 metres; and at 45° , and at sea-level, it is 9.806056 metres. Consequently, 760 mm. of mercury at 45° gives a pressure equal to that of 759.755 mm. at Paris; and this corresponds to a temperature of 99.9991°C .

In other words, the thermometer which is standard at 45° has each degree 0.99991 of the length of the degree of a thermometer standard at Paris.

To reduce Equation B to 45° latitude, we have

$$\log p = a + \log \frac{980.9218}{980.6056} - b\alpha^{0.00001t} + c\beta^{0.00001t};$$

and for Equation C ,

$$\begin{aligned} \log p &= a + \log \frac{980.9218}{980.6056} - b\alpha^{(0.00001t-100)} + c\beta^{(0.00001t-100)} \\ &= a + \log \frac{980.9218}{980.6056} - b\alpha^{-0.00001(t-100)} + c\beta^{-0.00001(t-100)}. \end{aligned}$$

The resulting equations which were used in calculating Table III are

B. For steam from 0° to 100°C . at 45° latitude.

$$\log p = a_1 - b_1\alpha_1^n + c_1\beta_1^n.$$

$$a_1 = 4.739502.$$

$$\log b = 0.6117400.$$

$$\log c = 8.13204 - 10.$$

$$\log \alpha_1 = 9.996725828 - 10$$

$$\log \beta_1 = 0.0068641.$$

$$n = t.$$

C. For steam from 100° to 220°C . at 45° latitude.

$$\log p = a_1 - b_1\alpha_1^n + c_1\beta_1^n.$$

$$a_1 = 5.457570.$$

$$\log b_1 = 0.4120021.$$

$$\log c_1 = 7.74168 - 10.$$

$$\log \alpha_1 = 9.997411296 - 10.$$

$$\log \beta_1 = 0.0076418.$$

$$n = t - 100.$$

equations for the pressure of steam, so that they will give the pressures in pounds on the square inch for degrees Fahrenheit, there are required the comparison of measures of length, and of weight, the comparison of the scales of the thermometers, and the specific gravity of mercury.

Professor Rogers (*Proceedings of the Am. Acad. of Arts and Sciences, 1882-83*, also *Additional Observations*, etc.) gives for the length of the metre, 39.3702 inches. This differs from the value given by Capt. Clarke (*Proceedings of the Royal Society, vol. xv., 1866*), by an amount that does not affect the values in the tables; his value being 39.370132 inches.

Professor Miller (*Phil. Transactions, cxlvi., 1856*) gives for the weight of one kilogram, 2.20462125 pounds.

Regnault gives, for the weight of one litre of mercury, 13.5959 kilograms. The degree Fahrenheit is $\frac{9}{5}$ of the length of the degree Centigrade.

$$\text{Let} \quad k = \frac{13.5959 \times 2.204621}{39.3702^2};$$

then the equations *B* and *C* have for the reduction to degrees Fahrenheit, and pounds on the square inch,

$$\log p = a_1 + \log k - b a_1^{\frac{5}{9}n} + c \beta_1^{\frac{5}{9}n},$$

$$\log p = a_1 + \log k - b_1 a_1^{\frac{5}{9}n} + c_1 \beta_1^{\frac{5}{9}n}.$$

The resulting equations, which were used in calculating Tables I and II, are:—

B. For steam from 32° to 212° F., in pounds on the square inch.

$$\log p = a_2 - b a_2^n + c \beta_2^n.$$

$$a_2 = 3.025908.$$

$$\log b = 0.6117400.$$

$$\log c = 8.13204 - 10.$$

$$\log a_2 = 9.998181015 - 10.$$

$$\log \beta_2 = 0.0038134.$$

$$n = t - 32.$$

C. For steam from 212° to 428° F., in pounds on the square inch.

$$\log p = a_2 - b_1 a_2^n + c_1 \beta_2^n.$$

$$a_2 = 3.743976.$$

$$\log b_1 = 0.4120021.$$

$$\log c_1 = 7.74168 - 10.$$

$$\log a_2 = 9.998561831 - 10.$$

$$\log \beta_2 = 0.0042454.$$

$$n = t - 212.$$

All of the foregoing equations make the pressure a function of the tem-

Other Equations for the Pressure of Steam.—Rankine, in his *Steam Engine and other Prime Movers*, gives the following equation:—

$$\log p = A - \frac{B}{T} - \frac{C}{T^2}.$$

For pounds on the square inch, corresponding to degrees Fahrenheit, —

$$A = 6.1007.$$

$$\log B = 3.43642.$$

$$\log C = 5.59873.$$

$$T = t + 461.^{\circ}2 \text{ F.}$$

This equation has been largely used for calculating tables on the English system. The following table will give a comparison between the results from this formula and those from Formulæ *B* and *C*.

| TEMPERATURE. | PRESSURE. | |
|--------------|---------------------------|----------|
| | Regnault at 45° latitude. | Rankine. |
| 32 | 0.0890 | 0.083 |
| 77 | 0.4555 | 0.452 |
| 122 | 1.7789 | 1.78 |
| 167 | 5.579 | 5.58 |
| 212 | 14.99 | 14.70 |
| 257 | 33.711 | 33.71 |
| 302 | 69.27 | 69.21 |
| 347 | 129.79 | 129.8 |
| 392 | 225.56 | 225.9 |
| 428 | 336.26 | 336.3 |

Differential Co-efficient $\frac{dp}{dt}$.—As will be seen later, the differential co-efficient $\frac{dp}{dt}$ is used in calculating the volume and density of saturated vapors.

From the general equation of the form,

$$\log p = a + ba^n + c\beta^n,$$

differentiation gives

$$\frac{1}{p} \frac{dp}{dt} = \frac{1}{M^2} b \log a \cdot a^n + \frac{1}{M^2} c \log \beta \cdot \beta^n,$$

in which *M* is the modulus of the common system of logarithms.

The equation may be written, —

$$\frac{1}{p} \frac{dp}{dt} = Aa^n + B\beta^n.$$

French units.

B. For 0° to 100° C., mm. of mercury,

$$\log A = 8.8512729 - 10.$$

$$\log B = 6.69305 - 10.$$

$$\log a_1 = 9.996725828 - 10.$$

$$\log \beta_1 = 0.0068641.$$

C. For 100° to 220° C., mm. of mercury.

$$\log A = 8.5495158 - 10.$$

$$\log B = 6.34931 - 10.$$

$$\log a_1 = 9.997411296 - 10.$$

$$\log \beta_1 = 0.0076418.$$

English units.

B. For 32° to 212° F., pounds on the square inch.

$$\log A = 8.5960005 - 10.$$

$$\log B = 6.43778 - 10.$$

$$\log a_2 = 9.998181015 - 10.$$

$$\log \beta_2 = 0.0038134.$$

C. For 212° to 428° F., pounds on the square inch,

$$\log A = 8.2942434 - 10.$$

$$\log B = 6.09403 - 10.$$

$$\log a_2 = 9.998561831 - 10.$$

$$\log \beta_2 = 0.0042454.$$

Heat of the Liquid and Specific Heat.—A preliminary series of experiments convinced Regnault that the specific heat of water at low temperature is unity. To test the specific heat at higher temperatures, he ran hot water from a boiler, and at a known temperature, into a calorimeter in which the temperature varied from 8° to 14° C., and the resulting upper temperature varied from 17° to 29° C. Knowing the original weight of water in the calorimeter, the weight run in from the boiler, and the initial and final temperatures in the calorimeter, he calculated the mean specific heat of water between the temperature of the boiler and the final temperatures of the calorimeter. A series of forty such experiments was made, with the temperature of the boiler varying from 108° to 192° C., from which Regnault concluded that the mean specific heat from 0° to 100° is 1.005; and from 0° to 200° , 1.016. The corresponding heat of the liquid, i.e., the heat required to raise one kilogram of water from 0° to a given temperature, t , is

and solving for the two constants by aid of the two known values of q , the following equation, which is commonly used, is deduced:—

$$q = t + 0.00002t^2 + 0.0000003t^3.$$

The specific heat at any temperature is, therefore,—

$$c = \frac{dq}{dt} = 1 + 0.00004t + 0.0000009t^2.$$

These equations are for use with the Centigrade scale; for the Fahrenheit scale, a given temperature may be reduced to the Centigrade scale, and then introduced in the same equations.

The process of making the experiments is really a complex one; for the water, in leaving the boiler, has work done on it by the steam pressure in the boiler, and it has a certain velocity impress on it at the same time, and again, in entering the calorimeter, it does work against the atmospheric pressure, and the kinetic energy of its motion is changed into heat. At higher temperatures there is a double change of state; part of the water changes to steam on leaving the boiler, and that steam is condensed again in the calorimeter. It is probable that the error of neglecting the effect of these several actions is inconsiderable.

The degree of accuracy to be accorded to this work is indicated by the fact that Regnault gives four significant figures in stating the data for the calculation of the constants in the equations.

Rowland's Experiments.—A series of experiments was made by Rowland at Baltimore, to determine the mechanical equivalent of heat, which gave a delicate method of determining the heat of the liquid, and the specific heat.

The apparatus used was similar to that used by Joule, with modifications to give greater certainty of results. The calorimeter was of larger size, and the paddle had the upper vanes curved like the blades of a centrifugal pump, to give a strong circulation up through the centre, past the thermometer for taking the temperatures, and down at the outside. The paddle was driven by a petroleum engine, and the power applied was measured by making the calorimeter into a friction brake, with two arms at which the turning moment was measured. Radiation was made as small as possible, and then was made determinate by use of a water-jacket outside of the calorimeter.

The experiments consisted essentially in delivering a measured amount of work to the water in the calorimeter, and in noting the rise of temperature produced thereby.

The whole range covered by the experiments was from 2° to 41° C. The results show that 430 kilogrammetres of work are required to raise one kilogramme of water from 2° to 3° C. Assuming that the same amount will be required to raise the same weight of water from 3° to 4°, 4° to 5°, 5° to 6°, 6° to 7°, 7° to 8°, 8° to 9°, 9° to 10°, 10° to 11°, 11° to 12°, 12° to 13°, 13° to 14°, 14° to 15°, 15° to 16°, 16° to 17°, 17° to 18°, 18° to 19°, 19° to 20°, 20° to 21°, 21° to 22°, 22° to 23°, 23° to 24°, 24° to 25°, 25° to 26°, 26° to 27°, 27° to 28°, 28° to 29°, 29° to 30°, 30° to 31°, 31° to 32°, 32° to 33°, 33° to 34°, 34° to 35°, 35° to 36°, 36° to 37°, 37° to 38°, 38° to 39°, 39° to 40°, 40° to 41°, the total work required to raise one kilogramme of water from 2° to 41° C. is 430 × 40 = 17200 kilogrammetres.

| 21 | 8997 | 426.2 | 21.065 | 21.064 | | | | | |

In the above table, column 1 gives the number of degrees above freezing on the Centigrade scale; column 2 gives the number of kilogrammetres required to raise one kilogramme of water from freezing point to the given temperature; column 3 is Rowland's mechanical equivalent of heat at the given temperature derived from 10° intervals on column 2; column 4 is obtained by dividing the numbers in column 2 by the mechanical equivalent of heat at 16 $\frac{2}{3}$ ° C., or 62° F., from column 3; and column 5 is calculated by considering the specific heat to be constant for each five degrees of temperature. These specific heats were derived from a curve obtained by plotting temperatures for abscissæ, and heats of the liquid for ordinates. The values of the specific heats will be given later, in connection with those for higher temperatures.

A review of the preceding table shows that the specific heat at low temperatures varies quite markedly, so that it appeared advisable to investigate the effect of this variation on Regnault's experiments already quoted. This was done quite expeditiously by multiplying the mean specific heat given by him for his several experiments by the true average specific heat for the range of temperature in the calorimeter. This corrected specific heat was

temperature of the boiler. The results were then plotted as before, and compared with the heats of the liquid derived from Regnault's mean specific heats uncorrected. The points by the corrected method were a little more regularly arranged than the points obtained by assuming the specific heat to be unity at low temperatures; but the improvement was inconsiderable. The inequality of the specific heat at low temperatures is seldom so much as the unavoidable errors of the method.

It appeared, that if the specific heat was assumed to be constant, from 40° to 45° , from 45° to 155° , and from 155° to 200° C., the straight lines thus drawn represented the experimental values as recalculated quite nearly; and, further, they represented the uncorrected experimental values more nearly than Regnault's equation.

Specific Heat of Water.—The combination of Rawland's and Regnault's experiments on the heat of the liquid by the method described gives the specific heats set down in the following table, Centigrade scale:—

| | | SPECIFIC HEAT. | | | |
|------|-------------|----------------|---|---|--------|
| From | 0° to 5° C. | 32° to 41° F. | . | . | 1.0072 |
| | 5° 10° | 41° 50° | . | . | 1.0044 |
| | 10° 15° | 50° 59° | . | . | 1.0016 |
| | 15° 20° | 59° 68° | . | . | 1. |
| | 20° 25° | 68° 77° | . | . | 0.9984 |
| | 25° 30° | 77° 86° | . | . | 0.9948 |
| | 30° 35° | 86° 95° | . | . | 0.9954 |
| | 35° 40° | 95° 104° | . | . | 0.9982 |
| | 40° 45° | 104° 113° | . | . | 1. |
| | 45° 155° | 113° 311° | . | . | 1.008 |
| | 155° 200° | 311° 392° | . | . | 1.016 |

Thermal Unit.—Heat is measured in calories, or British thermal units (*BTU*). A calorie commonly is defined as the heat required to raise one kilogramme of water from freezing point to 1° C.; and a British thermal unit, that required to raise one pound from 32° to 33° F. Nothing is known about the specific heat of water from 0° to 2° C.; consequently the commonly accepted value of the thermal unit is an ideal quantity inferred from the behavior of water at higher temperatures. It is more scientific to take an easily verified quantity for the standard; and there is a practical convenience in choosing 62° F. for the standard temperature, because it is near the mean temperature of the air during experimental work. Therefore, it is near the mean temperature in the calorimeter during ordinary work with that instru-

one pound of water from 62° to 63° F. This agrees substantially with the definition of the calorie, as the heat required to raise one kilogramme of water from 15° to 16° C.

In the tables for other vapors than steam, the old definition for the calorie, and Regnault's value for the heat of the liquid, are retained, to avoid entire recalculation.

Mechanical Equivalent of Heat.—The mechanical equivalent in metre-kilogrammes of one calorie at 16 $\frac{2}{3}$ ° C., deduced from Rowland's experiments in the third column of the table on page 58, is 427.1.

Since the value given by Joule is commonly quoted, it will be of interest to make a comparison of his latest work (1873) with Rowland's, as given in the following table:—

| Temperature. | Joule's Value at Manchester, English System. | Reduced to the Air Thermometer and to the Latitude of Baltimore. | | Rowland's Value, corresponding. |
|--------------|--|---|---------|------------------------------------|
| | | English. | French. | |
| 14.7° | 772.7 | 776.1 | 425.8 | 427.6 |
| 12.7° | 774.6 | 778.5 | 427.1 | 428.0 |
| 15.5° | 773.1 | 776.4 | 426.0 | 427.3 |
| 14.5° | 767.0 | 770.5 | 422.7 | 427.5 |
| 17.3° | 774.0 | 777.0 | 426.3 | 426.9 |

The value of g at Baltimore, latitude 39° 17', is 980.05 centimetres therefore, reducing to 45° of latitude, and at the sea level, the value of the mechanical equivalent of heat is

$$J = 426.9.$$

To reduce to the English system, multiply by $\frac{1}{3}$, and by the length of the metre in feet, so that

$$J = 778.$$

Total Heat.—This term is defined as the heat required to raise a unit of weight of water from freezing point to a given temperature, and to entirely evaporate it at that temperature. The experiments made by Regnault were in the reverse order; that is, steam was led from a boiler into the calorimeter, and there condensed. Knowing the initial and final weights of the calorimeter, the temperature of the steam, and the initial and final temperatures of the water in the calorimeter, he was able, after applying the necessary corrections, to calculate the total heats for the several experiments.

As a conclusion of the work, he gives the following values for the total heats:—

Assuming an equation of the form

$$\lambda = A + Bt,$$

Regnault calculated the constants from the values given for 100° and 195° , and gives the equation

$$\lambda = 606.5 + 0.305t.$$

Wishing to see the effect of the varying value of the specific heat at low temperatures, I recalculated the total heats given by experiment, by a method resembling that used in recalculation of the heats of the liquid, and plotted the results together with Regnault's values uncorrected. The recalculated points were a little more regular than the original ones, and lay nearer the line represented by the above equation. Especially did the recalculated points for those experiments, for which the true mean specific heat of the water in the calorimeter was nearly unity, lie near that line. It therefore appears that the equation represents our best knowledge of the total heat of steam.

For the Fahrenheit scale the equation becomes

$$\lambda = 1091.7 + 0.305(t - 32).$$

Heat of Vaporization.—If the heat of the liquid be subtracted from the total heat, the remainder is called the heat of vaporization, and is represented by r , so that

$$r = \lambda - q.$$

Internal and External Latent Heat.—The heat of vaporization overcomes external pressure, and changes the state from liquid to vapor at constant temperature and pressure. Let the specific volume of the saturated vapor be s , and that of the liquid be σ , then the change of volume is $s - \sigma = u$, on passing from the liquid to the vaporous state. The external work is

$$p(s - \sigma) = pu,$$

and the corresponding amount of heat, or the external latent heat, is

$$Ap(s - \sigma) = Apu,$$

A being the reciprocal of the mechanical equivalent of heat.

The heat required to do the disgregation work, or the internal latent heat, is

$$\rho = r - Apu.$$

Specific Volume and Density of Steam.—On account of the great difficulty of direct determination of the weight of saturated steam, it is customary to calculate the specific volume of steam by aid of the following equation, derived by the application of the principles of thermo-dynamics to the general

in which A is the reciprocal of the mechanical equivalent of heat, T is the temperature from the absolute zero, and σ is the volume of one unit of weight of the liquid from which the vapor is formed. The differential co-efficient $\frac{dp}{dt}$ can be calculated by aid of the equations on page 11.

The absolute temperature is obtained by adding 273.7 to the temperature in degrees Centigrade, or 460.7 to the temperature in degrees Fahrenheit.

The volumes and densities of saturated steam given in Tables I, II, and III, were calculated by this method.

It is of interest to consider the degree of accuracy that may be expected from this method of calculating the density of saturated vapor. The value of r depends on λ and q ; for the first, Regnault gives three figures in the data from which the empirical equation is deduced, and the experimental work does not indicate a greater degree of accuracy. The fourth figure, if stated, is likely to be in error to the extent of five units. The value of T is commonly stated in four figures, of which the last may be in error by two units. A , as determined by Rowland, has four figures, the last being uncertain to the extent of one or two units. The differential co-efficient $\frac{dp}{dt}$ is deduced from the equations for calculating p ; and those equations are derived from data having five places of significant figures. Now the Equations B and C , for steam at 45° of latitude for the English system give a pressure of 14.6967 pounds on the square inch; but the specific volume calculated by aid of Equation B is 26.550 cubic feet, while Equation C gives 26.637 cubic feet. The mean, 26.60, differs from either extreme by about one in seven hundred. This discrepancy is due to the fact that the curves represented by Equations B and C meet at the common temperature, 212°, but do not have a common tangent. Since the equations are empirical and not logical, the error or uncertainty is unavoidable, and all calculated specific volumes are affected by a similar uncertainty. The greatest probable error is in determining r , for which it may be about one in one thousand. The error introduced into this equation by using the values of A in common use, that is, 772 instead of 778, is about one in one hundred.

Tate and Fairbairn's Experiments.—In 1860 an attempt was made by Tate and Fairbairn to determine the specific volume of steam by direct experiment. The following table, taken from the *Philosophical Transactions*, Vol. cl., gives the results of all their experiments, together with the volumes calculated by their empirical formula,

| | Pressure in Inches of Mercury. P. | Maximum Temperature, Fahrenheit, of Saturation. T | Specific Volume from Experiments. V. | Specific Volume from Formula. V. | Error of Formula. |
|-----|--|---|---|---|----------------------|
| 1 | 5.35 | 136.77 | 8275.3 | 8183 | -92 |
| 2 | 8.02 | 155.33 | 5333.5 | 5326 | -7 |
| 3 | 9.45 | 159.36 | 4920.2 | 4900 | -20 |
| 4 | 12.47 | 170.92 | 3722.6 | 3700 | -22 |
| 5 | 12.61 | 171.48 | 3715.1 | 3710 | -5 |
| 6 | 13.62 | 174.92 | 3438.1 | 3478 | +40 |
| 7 | 16.01 | 182.30 | 3051.0 | 2985 | -66 |
| 8 | 18.36 | 188.30 | 2623.1 | 2620 | -3 |
| 9 | 22.88 | 198.78 | 2140.5 | 2124 | -16 |
| 1' | 53.61 | 242.90 | 943.1 | 937 | -6 |
| 2' | 55.52 | 244.82 | 908.0 | 906 | -2 |
| 3' | 55.80 | 245.22 | 892.5 | 900 | +7 |
| 4' | 66.84 | 255.50 | 750.4 | 758 | +8 |
| 5' | 76.20 | 263.14 | 649.2 | 669 | +20 |
| 6' | 81.53 | 267.21 | 635.3 | 628 | -7 |
| 7' | 84.20 | 269.20 | 605.7 | 608 | +3 |
| 8' | 92.23 | 274.76 | 584.4 | 562 | -22 |
| 9' | 90.08 | 273.30 | 563.2 | 515 | -48 |
| 10' | 99.00 | 279.42 | 515.0 | 519 | +4 |
| 11' | 104.54 | 282.58 | 467.2 | 496 | +29 |
| 12' | 112.78 | 287.25 | 458.3 | 461 | +3 |
| 13' | 122.25 | 292.53 | 433.1 | 428 | -5 |
| 14' | 114.25 | 288.25 | 440.6 | 456 | +16 |

It is apparent that the errors of this formula are much larger than the probable errors of the thermo-dynamic method.

The following table, giving the volumes in cubic metres of one kilogramme of saturated steam, shows the comparison of the two methods:—

| By equation | 0° C. | 50° C. | 100° C. | 150° C. | 200° C. |
|---|-------|--------|---------|---------|---------|
| $s = \frac{1}{AT} \cdot \frac{dA}{dP} + \sigma$ | 211.5 | 12.11 | 1.660 | 0.3875 | 0.1277 |

From equation

$$V = 25.62 + \frac{49153}{P + 0.72}, \quad 54.97 \quad 11.43 \quad 1.643 \quad 0.3706 \quad 0.1343$$

Steam Entropy.—From the second law of thermo-dynamics may be deduced the equation

$$d\phi = \frac{dQ}{T},$$

in which ϕ is the entropy, dQ is the heat applied or withdrawn, and T is the absolute temperature. Since the entropy depends on the state of the substance only, and not on the method of arriving at that state, we may calculate the increase of entropy in one unit of weight of a given mixture of water and steam, above the entropy at some initial state, by integrating the above

freezing point to the temperature t , and that the portion x is then changed into steam. During the first operation the change of entropy will be

$$\theta = \int_0^t \frac{dq}{T} = \int_0^t \frac{cdt}{T}.$$

During the second operation the change of entropy will be

$$\frac{xr}{T},$$

since the heat is added at the constant temperature t . The entire change of entropy will be

$$\phi = \frac{xr}{T} + \int_0^t \frac{cdt}{T} = \frac{xr}{T} + \theta.$$

At any other state the entropy of a unit of weight of a mixture of steam and water will be

$$\phi_1 = \frac{x_1 r_1}{T_1} + \theta_1,$$

and the change of entropy will be

$$\phi - \phi_1 = \frac{xr}{T} + \theta - \frac{x_1 r_1}{T_1} - \theta_1.$$

During an adiabatic change no heat is transmitted, and the entropy is constant.

$$\frac{xr}{T} + \theta = \frac{x_1 r_1}{T_1} + \theta_1.$$

When the initial state including the value of x is known, and also the final temperature or pressure, the final value of x_1 may be calculated by the above equation; and the initial and final volumes may be found by the equations

$$v = xu + \sigma, \quad v_1 = x_1 u_1 + \sigma;$$

the value of u for a given temperature or pressure, from the equation,

$$s = u + \sigma.$$

Entropy of the Liquid.—When the specific heat of a liquid is known in terms of the temperature, the entropy of the liquid,

$$\theta = \int_0^t \frac{cdt}{T},$$

is readily calculated. For water we have, for example, the entropy of the liquid at 13°C .

$$1.0072 \log_e \frac{T_6}{T_0} + 1.0044 \log_e \frac{T_{10}}{T_5} + 1.0016 \log_e \frac{T_{15}}{T_{10}}.$$

For other liquids having the general formula for the heat of the liquid,

$$q = at + bt^2 + ct^3,$$

Other Vapors.—Tables IV to IX are taken from Zeuner's *Mechanischen Wärmetheorie*. His values for the specific volume and density were calculated with 273 for the absolute temperature of 0° C., and with 424 for the mechanical equivalent of heat. To bring these tables into accord with Tables I, II, and III, the values of the specific volume and density have been modified by using 273.7 for the absolute temperature of 0° C., and 426.7 for the mechanical equivalent of heat at Paris.

The equations by which the tables were calculated, taken from Regnault's memoirs, *Académie des Sciences, Comptes rendus, Tome XXXVII*, are here assembled, together with Zeuner's equations for the differential co-efficient,

$$\frac{1}{p} \frac{dp}{dt}$$

TEMPERATURE AND PRESSURE.

| 1 | log p 2 | a 3 | b 4 | c 5 |
|------------------------|-----------------------|------------|-----------|-----------|

| Carbon tetrachloride . | 1.0007120 | 1.0040780 | 1+20 | -20°, +188° |

The equation for the temperature and pressure of the saturated vapor of acetone, as recalculated by Zeuner, is, —

$$\log p = a - ba^n + c\beta^n.$$

$$a = 5.3085419$$

$$\frac{1}{p} \frac{dp}{dt} = A\alpha^n + B\beta^n$$

From Zeuner's *Wärmetheorie*.

| | SIGN. | | Log ($A\alpha^n$) | Log ($B\beta^n$) |
|---------------------------------|-------------|------------|-------------------------------|-------------------------------|
| | $A\alpha^n$ | $B\beta^n$ | | |
| Alcohol | + | - | -1.1720041-0.0029143 <i>t</i> | -2.9992701-0.0590515 <i>t</i> |

| Chloroform | + | + | -1.3410130-0.0025856 <i>t</i> | -2.0067124-0.0131824 <i>t</i> |
| Carbon bisulphide | + | + | -1.4339778-0.0022372 <i>t</i> | -2.0511078-0.0088003 <i>t</i> |
| Carbon tetrachloride, | + | + | -1.8611078-0.0002880 <i>t</i> | -1.3812195-0.0050220 <i>t</i> |
| Aceton | + | + | -1.3268535-0.0026148 <i>t</i> | -1.9064582-0.0215592 <i>t</i> |

HEAT OF THE LIQUID.

| | |
|--------------------------------|--|
| Alcohol | $q = 0.54754t + 0.0011218t^2 + 0.000002206t^3$ |
| Ether | $q = 0.52901t + 0.0002959t^2$ |
| Chloroform | $q = 0.23235t + 0.0000507t^2$ |
| Carbon bisulphide | $q = 0.23523t + 0.0000815t^2$ |
| Carbon tetrachloride | $q = 0.19798t + 0.0000906t^2$ |
| Aceton | $q = 0.50643t + 0.0003965t^2$ |

TOTAL HEAT.

| | |
|--------------------------------|--|
| Ether | $\lambda = 94 + 0.45t - 0.00055556t^2$ |
| Chloroform | $\lambda = 67 + 0.1375t$ |
| Carbon bisulphide | $\lambda = 90 + 0.14601t - 0.0004123t^2$ |
| Carbon tetrachloride | $\lambda = 52 + 0.14625t - 0.000172t^2$ |
| Aceton | $\lambda = 140.5 + 0.36644t - 0.000516t^2$ |

The total heat of alcohol varies in so irregular a manner that no equation can be given for it.

Zeuner gives the following empirical equations for calculating the heat equivalent of the internal work, which are proposed to lessen the labor of calculation

HEAT EQUIVALENT OF INTERNAL WORK.

| | |
|--------------------------------|---|
| Water | $\rho = 575.40 - 0.791t$ |
| Ether | $\rho = 86.54 - 0.10648t - 0.0007160t^2$ |
| Chloroform | $\rho = 62.44 - 0.11282t - 0.0000140t^2$ |
| Carbon bisulphide | $\rho = 82.79 - 0.11446t - 0.0004020t^2$ |
| Carbon tetrachloride | $\rho = 48.57 - 0.06844t - 0.0002080t^2$ |
| Aceton | $\rho = 131.63 - 0.20184t - 0.0006280t^2$ |

Sulphur Dioxide and Ammonia.—The use of ice-machines has brought into prominence liquids which vaporize at low temperatures. For two such

SULPHUR DIOXIDE.

$$\log p = a - ba^n - c\beta^n$$

$$a = 5.6663790$$

$$b = 3.0146890$$

$$c = 0.1465400$$

$$\log a = \bar{1}.9972989$$

$$\log \beta = \bar{1}.9872900$$

$$n = t + 28$$

$$\text{Limits, } -28, +62.$$

AMMONIA.

$$\log p = a - ba^n - c\beta^n$$

$$a = 11.5043330$$

$$b = 7.4503520$$

$$c = 0.9499674$$

$$\log a = \bar{1}.9996014$$

$$\log \beta = \bar{1}.9939729$$

$$n = t + 22$$

$$\text{Limits, } -22, +82.$$

Unfortunately the heat of the liquid and the total heat for these substances have not been determined. We have, however, some of the properties of these substances in the gaseous state or more properly in the state of superheated vapors.

Now, it has been shown by Zeuner that superheated steam may have its properties represented by the equation

$$pv = BT - Cp^a,$$

in which p is the pressure in pounds on the square foot or kilograms on the square meter, v is the volume of a pound in cubic feet or of a kilogram in cubic meters, and T is the absolute temperature. The constants have the following values when calculated from the properties of saturated steam:

$$\text{French units, } B = 51.3 \quad C = 198 \quad a = \frac{1}{4}.$$

$$\text{English units, } B = 93.5 \quad C = 971 \quad a = \frac{1}{4}.$$

It was first proposed by Ledoux to find similar equations to represent the properties of superheated sulphur dioxide and ammonia, and to use such equations for calculating approximate tables of the properties of these vapors when saturated, just as the tables of the properties of saturated steam had been used in establishing the equation for superheated steam.

In the *Thermodynamics of the Steam-engine* by the author, pages 452 to 459, this calculation has been carried out with the best ascertained properties of the superheated vapors of sulphur dioxide and ammonia with the following results:

SULPHUR DIOXIDE.

$$\text{French units, } pv = 14.5 \quad T - 48p^{0.22}$$

$$\text{English units, } pv = 26.4 \quad T - 184p^{0.22}$$

AMMONIA.

$$pv = 54.3 \quad T - 142p^{\frac{1}{3}}$$

$$pv = 99 \quad T - 540p^{\frac{1}{3}}$$

The application of these equations to the vapors when saturated gives

| | SULPHUR DIOXIDE. | AMMONIA. |
|----------------|--------------------------|-------------------------|
| French units, | $r = 98 - 0.27t$ | $r = 300 - 0.8t$ |
| English units, | $r = 176 - 0.27(t - 32)$ | $r = 540 - 0.8(t - 32)$ |

SPECIFIC HEAT OF THE LIQUID.

| SULPHUR DIOXIDE. | AMMONIA. |
|------------------|-----------|
| $c = 0.4$ | $c = 1.1$ |

Tables X and XI were calculated by aid of the equations written, and may be of use for approximate calculations, in default of more reliable tables.

Specific Volume of Liquids.—Table XII was taken from the *Phys.-Chem. Tabellen* of Landolt and Börnstein.

Volume of Water.—Table XIII gives the volumes of water compared with its volume at 4°. From 0° to 100° C., the values are those given by Rossetti. Above 100°, the values are those calculated by the equations given by Hirn in the *Annales de Chimie et de Physique*, 1867.

Volumes of Liquids.—The volumes of liquids at high temperatures, compared with the volume at freezing point, are represented by the following equations given by Hirn in the *Annales*:—

| Water 100° C. to 200° C. (vol. at 4° C.= unity) | | Logs. |
|--|--|--------------|
| $v = 1 + 0.00010867875t$ | | 0.0361445—10 |
| $+ 0.0000030073653t^2$ | | 4.4781862—10 |
| $+ 0.0000000028730422t^3$ | | 1.4583419—10 |
| $- 0.000000000066457031t^4$ | | 8.8225409—20 |
| Alcohol 30° C. to 160° C. (vol. at 0° C.= unity) | | |
| $v = 1 + 0.00073892265t$ | | 0.8685901—10 |
| $+ 0.00001055235t^2$ | | 3.0234492—10 |
| $- 0.000000002480842t^3$ | | 2.4660517—10 |
| $+ 0.00000000040413567t^4$ | | 0.6065278—10 |
| Ether 30° C. to 130° C. (vol. at 0° C.= unity) | | |

Other Data. — For convenience the following data are assembled: —

| | |
|---|--|
| Length of the metre in inches | { 39.3702 (Rogers) 39.370432 (Clarke) |
| Weight of the kilogramme in pounds | 2.20462125 |
| Weight of 1 litre (1 cn. decimetre) of mercury | 13.5959 kilos. |
| One horse power, in foot pounds per second | 550 |
| <i>Cheval à vapeur</i> , in kilogrammetres per second | 75 |
| Normal pressure of the atmosphere | { 760 mm. of mercury. 10,333 kilos per sq. m. 14.6967 lbs. per sq. in. 2116.32 lbs. per sq. ft. |
| Absolute temperature of freezing point | { 273. [°] C. 492. [°] F. |

Explanation of the Tables. — In Table I, the first column gives the temperature, t , of saturated steam.

The second column gives the corresponding pressure, p , in pounds on the square inch, above an absolute vacuum; the differences are placed between the two numbers from which they are derived. For example, the pressure at 40° F. is 0.1216 pounds per square inch; and the difference to be used in interpolation, and placed half a line lower, is .48.

The third column gives the heat of the liquid, q , required to raise the temperature of one pound of water from 32° F. to a given temperature.

The fourth column gives the total heat, λ , required to raise one pound of water from 32° F. to a given temperature, and to entirely vaporize it under the pressure due to that temperature.

The fifth column gives the heat of vaporization, or the heat required to vaporize one pound of water at a given temperature, under the pressure corresponding.

The sixth column gives the heat required to do the disgregation work during the vaporization of one pound of water.

The seventh column gives the heat required to overcome the external pressure, and do the work of increasing the volume from σ to s .

The eighth column gives the entropy of the liquid.

The ninth and tenth columns give the specific volume, or volume in cubic feet, of one pound of saturated steam, and the density or weight of one cubic foot in pounds.

Table II differs from Table I in that it is arranged to give the properties of saturated steam for each pound of pressure.

Table III gives the properties of saturated steam in French units; and Tables IV to XI give the properties of other saturated vapors in the same

TABLE I.

SATURATED STEAM.

TABLE XII.

SPECIFIC GRAVITY AND SPECIFIC VOLUME OF LIQUIDS.

| Name of Liquid. | Specific Gravity, compared with Water at 4° C. | Specific Volume, Cubic Meters per Kilo. |
|---|--|---|
| Alcohol, C_2H_6O | 0.80025 [Mendelejeff, 1869] | 0.001240 |
| Ether, $C_4H_{10}O$ | 0.736 [Kopp, 1860] | 0.001358 |
| Chloroform | 1.527 [Thorpe, 1880] | 0.000655 |
| Carbon bisulphide, CS_2 | 1.2022 [Thorpe, 1880] | 0.000774 |
| Carbon tetrachloride, CCl_4 | 1.6320 [Thorpe, 1880] | 0.000613 |
| Aceton, C_3H_6O | 0.81 [Zander, 1882] | 0.00123 |
| Sulphur Dioxide SO_2 | 1.4336 [Andréeff, 1859] | 0.0006081 |
| Ammonia NH_3 | 0.6304 [Andréeff, 1859] | 0.001571 |
